4. Install drip edge miters first. Hook the hem of the drip edge over the cleat and rotate it back onto the roof, taking care to engage both miter legs on the cleat. Secure miter through the roof flange with provided 1 ½" ring shank nails. Install one nail through each slotted hole.

5. Plan drip edge layout to avoid cutting any section shorter than 5'-0" if possible, and to balance joints with cut sections at the center or both ends of a run. Apply sealant on the face of the installed splices. Position splice in the opposite end of the drip edge as per step 3. Hook the hem of the drip edge over the cleat and rotate it back onto the roof and over the installed splice. Position the drip edge to leave a 1/4" gap between sections for expansion. Secure drip edge through the roof flange with provided 1 1/2" ring shank nails. Install one nail through each slotted hole.

6. Strip-in Drip Edge roof flange per membrane manufacturer's recommendations.
